"The simplest theories in population genetics are those which clearly are not true" Dr Bruce Weir

# Mixed populations 

DNA Statistics Workshop<br>ISFG<br>2007

A hypothetical example to demonstrate a potential situation

|  | Carlings | Catts | $100: 100$ <br> mix |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| AA | 81 | 1 |  |  |  |
| Aa | 18 | 18 |  |  |  |
| aa | 1 | 81 |  |  |  |
|  | 100 | 100 |  |  |  |

A hypothetical example to demonstrate a potential situation

|  | Carlings | Catts | $100: 100$ <br> mix | Expected |  |
| :---: | :---: | :---: | :---: | :---: | :--- |
| AA | 81 | 1 | 82 |  |  |
| Aa | 18 | 18 | 36 |  |  |
| aa | 1 | 81 | 82 |  |  |
|  | 100 | 100 | 200 |  |  |

## Calculation HW expectations

- Generate the allele frequencies
- Count the allele/total alleles
- Apply $p^{2}$ and $2 p q$

A hypothetical example to demonstrate a potential situation

|  | Carlings | Catts | $100: 100$ <br> mix | Expected |
| :---: | :---: | :---: | :---: | :---: |
| AA | 81 | 1 | 82 | $2 \times 82+36=200$ |
| Aa | 18 | 18 | 36 | $200 / 400=0.5$ <br> $\mathrm{pA}=0.5$ |
| aa | 1 | 81 | 82 | $\mathrm{Pa}=0.5$ |
|  | 100 | 100 | 200 |  |

## A hypothetical example to demonstrate a potential situation

|  | Carlings | Catts | $100: 100$ <br> mix | Expected |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| AA | 81 | 1 | 82 | $0.5^{2}=0.25$ | $0.25 \times 200$ <br> $=50$ |
| Aa | 18 | 18 | 36 | $2 \times 0.5 \times 0.5$ <br> $=0.5$ |  |
| aa | 1 | 81 | 82 | $0.5^{2}=0.25$ |  |
|  | 100 | 100 | 200 | 1 |  |

A hypothetical example to demonstrate a potential situation

|  | Carlings | Catts | $100: 100$ <br> mix | Expected |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| AA | 81 | 1 | 82 | 50 |  |
| Aa | 18 | 18 | 36 | 100 |  |
| aa | 1 | 81 | 82 | 50 |  |
|  | 100 | 100 | 200 | sum |  |

A hypothetical example to demonstrate a potential situation

|  | Carlings | Catts | $100: 100$ <br> mix | Expected |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| AA | 81 | 1 | 82 | 50 | $\mathbf{4}$ |
| Aa | 18 | 18 | 36 | 100 | $\downarrow$ |
| aa | 1 | 81 | 82 | 50 | $\mathbf{4}$ |
|  | 100 | 100 | 200 |  |  |

## Mixed populations - summary

- This example was deliberately very extreme
- Real populations show much lesser effects
- Called the Wahlund principle
- Wahlund, S., Zuzammensetzung von populationen und korrelationserscheinungen vom standpunkt der vererbungslehre aus betrechtet. Hereditas, 1928. 11: p. 65106.
- Homozygote excess
- Heterozygote deficiency but some may be each way

## Wahlund effect

## CES

In large populations which contain sub-populations ther are fewer homozygotes tha) in th the set of subdivided populations. This is a general, and athematically automatic, esult. increased frequency of homozygotes in subdivided populations is called the whund effect

The Wahlund effect has a number of important consequences:

## General population or separate databases?

- Hd: The suspect is NOT the donor of the stain.
- $\operatorname{Pr}(\mathrm{E} \mid \mathrm{Hd})$ probability of the evidence IF the suspect is not the donor of the stain.
- So the stain has come from someone else?
- So he can be anyone from the total (general) population.
- So we really do want to model the general population.

## Fisher's exact test

- Considered superior for large sparse contingency tables
- This is the DNA situation

## The formula

test statistic $=\frac{n!2^{n A B+n A C+n B C} n_{A}!n_{B}!n_{C}!}{(2 n)!n_{A A}!n_{B B}!n_{C C}!n_{A B}!n_{A C}!n_{B C}!}$

## Fisher's exact test procedure

- We will calculate the test statistic
- We need to know if this is big (usual) or small (unusual)
- We will shuffle the data ensuring independence
- We will calculate the test statistic for these shuffles
- We will compare

## The procedure

- recover the allele counts
- calculate the formula
- shuffle the alleles and calculate again
- do this a number of times
- order the shuffled sets and see if the real dataset is in the unusual $1 \%$ or $5 \%$ of shuffled sets

## Example

Consider the following ridiculously small dataset
write on board

| individual | genotype |
| :---: | :---: |
| 1 | AA |
| 2 | AA |
| 3 | AA |
| 4 | BB |
| 5 | BC |

## Step 1: recover the allele counts

- There are six A’s
- three B's
- one C
- Done

## Step 2: calculate the formula

## $10!3!1!0!0!0!1$ ! $=0.0476$

## Step 3: shuffle the alleles

| individual | genotype |
| :---: | :---: |
| 1 | AA |
| 2 | AA |
| 3 | AB |
| 4 | BB |
| 5 | AC |

## Step 3 cont: calculate the formula

test statistic $=5!{ }^{21+1+0} 6!3!1!$ 10!2!1!0!1!1!0! $=0.286$

## Step 5: Order the shuffled datasets

- I only did one shuffle. We normally do thousands by the computer.
- In fact I had done three shuffles giving probabilities 0.286, 0.286 and 0.380
- The real data gave a probability of 0.0476
- So the real data is the most unusual of these shuffles

## Class exercise

- A volunteer to be real
- Please take the 20 "alleles" given and shuffle them
- Make 10 people from these alleles
- Calculate the formula for your set

## Dependence testing

- At the moment we test for dependence at each locus (H-W)
- We test for pairwise independence at each pair of loci
- We can test triples and higher but the power of the tests declines

## Validating the population genetic model

- It is wrong to assume independence testing measures departure
- A large $p$-value (close to 1 ) for a small dataset is not proof of independence, nor does it prove that the population must be close to independence
- in a large dataset we expect to find small departures from HWE

## Validating the population genetic model

- Multitesting
- For 13 loci
- there will be 13 Hardy-Weinberg tests
- and tests $\mathrm{N}(\mathrm{N}-1) / 2=78$ between pairs of loci
- Because $5 \%$ of our tests will give false positives we expect about 5\% x (13+78)

## Validating the population genetic model

- Even our best tests for dependence are weak

## Power estimates for the Exact test

|  | Sample Size |  |
| :---: | :---: | :---: |
| $\theta$ | $\mathbf{8 0}$ | $\mathbf{2 0 0}$ |
| 0.00 | $5 \%$ | $5 \%$ |
| 0.01 | $6 \%$ | $6 \%$ |
| 0.03 | $8 \%$ | $11 \%$ |

Hence we often do not detect the departure $\rightarrow$ false negatives

NSW Aboriginal $n=5116$ or 5114 alleles

| Locus | $\boldsymbol{p}$-value |
| :--- | :---: |
| D3 | 0.786 |
| VWA | 0.155 |
| FGA | 0.531 |

Figure 2D: p-p plot for the NT Declared Aboriginal sub-population

p-p plot for the New South Wales Aboriginal Australian Dataset

## What is the $p$-value ?

- The nearest thing is $\operatorname{Pr}($ data|HW) or $\operatorname{Pr}($ data|LE)
- NOT
- $\operatorname{Pr}$ (HW|data) or $\operatorname{Pr}($ LE $\mid$ data $)$
- This is a famous error.

## Mixed populations - summary

- The example was deliberately very extreme
- Real populations show much lesser effects
- Called the Wahlund principle
- Wahlund, S., Zuzammensetzung von populationen und korrelationserscheinungen vom standpunkt der vererbungslehre aus betrechtet. Hereditas, 1928. 11: p. 65106.
- Homozygote excess
- Heterozygote deficiency but some may be each way

## IBD states

- Two alleles that are copies of the same ancestral allele and said to be identical by descent, IBD.

# Charles has blue eyes - bb 

You won't ever need this - probably
Consider an individual
Either the two alleles are IBD OR they are not
$\mathrm{F}_{\text {IT }}$ or F

$$
\begin{aligned}
\operatorname{Pr}(\mathrm{AA}) & =\mathrm{F} \times \operatorname{Pr}(\mathrm{A})+(1-\mathrm{F}) \times \operatorname{Pr}(\mathrm{A})^{2} \\
& =\mathrm{FPr}(\mathrm{~A})+\operatorname{Pr}(\mathrm{A})^{2}-\mathrm{F} \operatorname{Pr}(\mathrm{~A})^{2} \\
& =\operatorname{Pr}(\mathrm{A})^{2}+\operatorname{Pr}(\mathrm{A}) \mathrm{F}(1-\operatorname{Pr}(\mathrm{A})) \\
\operatorname{Pr}(\mathrm{AB}) & =(1-\mathrm{F}) \times 2 \operatorname{Pr}(\mathrm{~A}) \operatorname{Pr}(\mathrm{B}) \\
& =2(1-\mathrm{F}) \operatorname{Pr}(\mathrm{A}) \operatorname{Pr}(\mathrm{B})
\end{aligned}
$$

## Recommendation 4.1

$$
\begin{aligned}
& \operatorname{Pr}(\mathrm{A} \mathrm{~A})=\operatorname{Pr}(\mathrm{A})^{2}+\mathrm{F} \operatorname{Pr}(\mathrm{~A})(1-\operatorname{Pr}(\mathrm{A})) \\
& \operatorname{Pr}(\mathrm{AB})=2 \operatorname{Pr}(\mathrm{~A}) \operatorname{Pr}(\mathrm{B})
\end{aligned}
$$

## Recommendation 4.1

- Might work OK if
- The allele probabilities were known exactly
- The population was in LE
- We will show practical tests later

## Adding subpopulation correction

- You have been studying Aboriginals for a while
- Pretty much P(A) has been about $10 \%$
- You find a new tribe?
- What do you estimate $\mathrm{P}(\mathrm{A})$ to be before you sample any?
- You sample an AA homozygote
- AA
- AA
- AA

## Adding subpopulation correction

- There are two methods
- Sampling formula
- Cheating rules
- You only need to know one
- They both give the same answer
- But for your scientific cred. you might need to know that the other exists

## Change to a formula

- Wherever you see the first A $(1-\theta) \mathrm{P}_{\mathrm{a}}$
- 2nd A $\quad \theta+(1-\theta) \mathrm{P}_{\mathrm{a}}$
- 3rd A $2 \theta+(1-\theta) \mathrm{P}_{\mathrm{a}}$
- 4th A $3 \theta+(1-\theta) \mathrm{P}_{\mathrm{a}}$
- 5th A $4 \theta+(1-\theta) \mathrm{P}_{\mathrm{a}}$

## Over a correction term

- 2 alleles in front and 2 behind the bar $(1+\theta)(1+2 \theta)$
- 2 in front 4 behind $(1+3 \theta)(1+4 \theta)$
- 2 in front 6 behind $(1+5 \theta)(1+6 \theta)$
- 4 in front 6 behind $(1+5 \theta)(1+6 \theta)(1+7 \theta)(1+8 \theta)$

## Generalising the correction term

- N alleles in front and M behind
- write
- $(1+\{\mathrm{M}-1\} \theta) \ldots . .$.
- $(1+\{\mathrm{N}+\mathrm{M}-3\} \theta)(1+\{\mathrm{N}+\mathrm{M}-2\} \theta)$

## Adding subpopulation effects

Consider $\operatorname{Pr}(\mathrm{aa} \mid \mathrm{aa})$ or $\operatorname{Pr}(\mathrm{ab} \mid \mathrm{ab})$

3rd A

4th A

# $\operatorname{Pr}(a b \mid a b)=\frac{2\left(\theta+(1-\theta) P_{a}\right)\left(\theta+(1-\theta) P_{b}\right)}{(1+\theta)(1+2 \theta)}$ <br> $$
(1+\theta)(1+2 \theta)
$$ 

Balding, D. J. and R. A. Nichols (1994). "DNA profile match probability calculations : how to allow for population stratification, relatedness, database selection and single bands." Forensic Science International 64: 125-140.

## This approach

- Compensates for HW and LE disequilibria caused by subpopulations
- Compensates for some uncertainty in the relevant population
- Weight-of-Evidence for Forensic DNA Profiles D. J. Balding ISBN: 0-470-86764-7 Hardcover 192 pages March 2005

- Forensic DNA Evidence Interpretation. Buckleton, Triggs and Walsh. CRC Press. Boca Rayton, Florida. 2005.

## Recommendation 4.2

homozygotes

$$
\begin{aligned}
& \frac{(2 \theta+(1-\theta) p)(3 \theta+(1-\theta) p)}{(1+\theta)(1+2 \theta)} \\
& \frac{2(\theta+(1-\theta) p)(\theta+(1-\theta) q)}{(1+\theta)(1+2 \theta)}
\end{aligned}
$$

## Choice of population genetic model

- Do
- Consider the history and diversity of your population
- Consider the results of other samples within your population or related ones
- Don’t
- Over rely on independence testing

## Population Genetic models

- The product rule - may lead to discussion in court of independence testing and population subdivision
- Recommendation 4.1 - may lead to discussion in court of independence testing and population subdivision
- Recommendation 4.2 - may lead to discussion of the value for theta

Recommendation $4.1 \quad \theta=0.03$

Recommendation $4.2 \theta=0.03$

## I would be very worried if you used a model when you knew the assumptions were not met

## But because we think it makes good predictions even when they are not met

John Buckleton ESR

## That is different. I see. Can you prove it?

$$
\begin{aligned}
& \theta_{\mathrm{x}}=5 \% \\
& \theta_{\mathrm{z}}=3 \% \\
& \theta_{\text {calc }}=3 \%
\end{aligned}
$$

## TECHNICAL NOTE

The trick is to be able to factor in subpopulation effects and relatives into the expected

$$
\begin{gathered}
P_{0}=\frac{(1-\theta)}{4(1+\theta)(1+2 \theta)}\left[1-(2-\theta)\left\{(2-\theta) \sum_{a} p_{a}^{2}+2(1-\theta) \sum_{a} p_{a}^{3}\right\}+(1-\theta)^{2}\left\{2\left(\sum_{a} p_{a}^{2}\right)^{2}-3 \sum_{a} p_{a}^{4}\right\}\right] \\
\left.P_{1}=\frac{(1-\theta)}{(1+\theta)(1+2 \theta)}\left[(1+\theta)(1+4 \theta)+\left[1-7 \theta-4 \theta^{2}\right] \sum_{a} p_{a}^{2}+2(1-\theta)\left\{\sum_{a} p_{a}^{3}-(1-\theta)\left\{\left(\sum_{a} p_{a}^{2}\right)^{2}+\sum_{a} p_{a}^{4}\right\}\right\}\right]\right] \\
P_{2}=\frac{1}{4(1+\theta)(1+2 \theta)}\left[\begin{array}{l}
(1+2 \theta)\left[1+3 \theta+4 \theta^{2}\right]+ \\
\left.(1-\theta)\left\{\begin{array}{l}
\sum_{a} p_{a}^{2}\left\{\left[2+10 \theta+9 \theta^{2}\right]+2(1-\theta)^{2}\left(\sum_{a} p_{a}^{2}\right)\right\} \\
+(1-\theta)\left\{2 \theta \sum_{a} p_{a}^{3}-(1-\theta)^{2} \sum_{a} p_{a}^{4}\right\}
\end{array}\right\}\right]
\end{array}\right.
\end{gathered}
$$

Aboriginal data

$\mathrm{N}=8,634$

This is great news for the robustness of the model.

## The frequency based on the product rule is 1 in a million

What is the error in that estimate due to subpopulation effects?

Not a lot

## What's a lot?

## Nothing of significance.

Please confine yourself to giving scientific facts. I'm here to determine significance.

The frequency of this profile is not more than 1 in a 500,000

What is the error in that estimate due to subpopulation effects?

## Any reasonable doubt has been conceded to the defendant.

Thank you for this very balanced evidence

Actually your honour are you aware that it took me twice as long to calculate and that I have had to have extensive training to do this.

Not really but I do like you taking the burden of this type of decision on yourself as scientific doubt is your province not mine.

End

[^0]:    * $x$ loci with two alleles matching, $y$ loci with one allele matching.
